Intermolecular Energies

- ▶ Supermolecular approach

$$E_{int} = E_{AB} - E_A - E_B$$

  - ▶ Straightforward, but cannot separate different types of interactions
  - ▶ Can adopt to different electronic structure methods
  - ▶ DFT-D3 with proper functional can be both cheap and accurate
- ▶ Symmetry-Adapted Perturbation Theory
  - ▶ Can give details about different types of interactions; important in understanding their nature
  - ▶ Not as cheap as DFT-D3
  - ▶ SAPT0 is somewhat cheap, but does not include intramonomer correlation

SAPT(DFT)

- ▶ Attempt to inlude intramonomer correlation in a cheap way
- ▶ Replaces HF orbitals with KS orbitals
- ▶ Needs to consider orbital response for dispersion terms
- ▶ Exchange-dispersion term needs to be estimated from scaling
- ▶ Investigate the accuracy and efficiency of SAPT(DFT)

Three-Body Interaction

- Crucial in computing lattice energies
- DFT-D3 does not perform well for three-body interaction
- MP2.5 scales as $O(N^6)$, MP2 is $O(N^5)$ but lacks three-body dispersion
- Three-body dispersion can be implemented with SAPT(DFT) in $O(N^5)$
- Combine MP2 with SAPT(DFT) dispersion to model three-body interaction

Georgia Tech

Idea of SAPT(DFT)

▶ SAPT energy in orders of interaction and fluctuation potentials; n denotes order in V and k, l for W_A, W_B

$$H = F_A + F_B + V + W_A + W_B$$

$$E_{int} = \sum_{n=1}^{\infty} \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} \left(E_{pol}^{(nkl)} + E_{exch}^{(nkl)} \right)$$

▶ SAPT0: $n = 2, k = l = 0$, no intramonomer correlation, $O(N^5)$ cost

▶ Many-body SAPT: $k, l \geq 2$, $O(N^7)$ or higher cost

▶ SAPT(DFT): Use Kohn-Sham operator $K_{A,B}$ instead of Fock operator $F_{A,B}$, $O(N^5)$ cost

▶ Primitive SAPT(DFT) works well on 1st-order terms, but not 2nd-order terms (especially dispersion). Needs orbital response for them

Dispersion Term

- ALDA kernel good for pure GGA functional, but not for hybrid functional
- Exact exchange in $v_{xc} \rightarrow$ increased $\epsilon_{ij}^{ab} \rightarrow$ decreased $E_{disp}^{(2)}$

$$E_{disp,u}^{(2)} = -4 \sum_{ia \in A, jb \in B} \frac{|(ia|jb)|^2}{\epsilon_{ij}^{ab}}$$

- Hybrid ALDA kernel to compensate, or localized HF (LHF) exchange to avoid increase in ϵ_{ij}^{ab}

$$f_{xc} = \alpha f_{xc}^{HF} + (1 - \alpha) f_{xc}^{ALDA}$$

Georgia
Tech

Equation for $E_{disp}^{(2)}$

► Computing coupled FDDS:

$$\boldsymbol{\chi} = \boldsymbol{\chi}_0' + \left(\boldsymbol{\chi}_0' \mathbf{S}^{-1} \mathbf{W} + \mathbf{K}\right) \left[\mathbf{S} - \left(\boldsymbol{\chi}_0' \mathbf{S}^{-1} \mathbf{W} + \mathbf{K}\right)\right]^{-1} \boldsymbol{\chi}_0'$$

$$\boldsymbol{\chi}_0' = \boldsymbol{\chi}_0 - \alpha \mathbf{K}_2 \left(\lambda\right)$$

$$\mathbf{K} = \left[-\alpha \mathbf{K}_1 \left(\lambda d\right) - \alpha \mathbf{K}_2 \left(\lambda d\right) + \alpha^2 \mathbf{K}_{21} \left(\lambda\right)\right] \left(\mathbf{R}^t\right)^{-1} \mathbf{S}$$

► $O(N^5)$ scaling is limited to forming $\mathbf{K}_1$, $\mathbf{K}_2$ and $\mathbf{K}_{21}$

► Separates nontrivial and trivial parts of the code, also highly reduces need of disk I/O operations

► $E_{disp}^{(2)}$ from coupled FDDS:

$$E_{disp}^{(2)} = -\frac{1}{2\pi} \int_0^\infty d\omega \int d\mathbf{r}_A d\mathbf{r}_A' d\mathbf{r}_B d\mathbf{r}_B'$$

$$\frac{1}{|\mathbf{r}_A - \mathbf{r}_B|} \frac{1}{|\mathbf{r}_A' - \mathbf{r}_B'|} \chi^A \left(\mathbf{r}_A, \mathbf{r}_A' | i\omega\right) \chi^B \left(\mathbf{r}_B, \mathbf{r}_B' | i\omega\right)$$

Exchange-Dispersion Term

- Coupled exchange-dispersion requires storing 4-index tensors on disk
- Estimate from scaling uncoupled exchange-dispersion; Scale with ratio in dispersion term or with pre-fitted (with S22×5) fixed factor

$$\tilde{E}^{(2)}_{exch-disp,r} = E^{(2)}_{exch-disp,u} \cdot \frac{E^{(2)}_{disp,r}}{E^{(2)}_{disp,u}}$$

$$\tilde{E}^{(2)}_{exch-disp,r} = \alpha \cdot E^{(2)}_{exch-disp,u} (\alpha = 0.686361)$$

- The value above is fitted from $E^{(2)}_{exch-disp,u}$ with LHF orbitals
- Non-LHF orbitals have greater o-v gaps and smaller $E^{(2)}_{disp,u}$, needs to re-fit with non-LHF results
LHF vs non-LHF orbitals

Figure: Hybrid vs. LHF values for each term for S66 data set ($E_{elst}^{(1)}$, $E_{exch}^{(1)}$, $E_{ind}^{(2)}$, $E_{exch-ind}^{(2)}$, $E_{disp,r}^{(2)}$, $E_{disp,u}^{(2)}$, $E_{exch-disp,u}^{(2)}$)

Georgia Tech

GRAC

- (Hybrid-)GGA functionals does not have correct long-range behavior $v_{xc}(r) \rightarrow -1/r + (I_p + \epsilon_{\text{HOMO}})$
- Underestimates o-v gap as a consequence
- Functionals like LB94 have correct asymptotic behavior, but poor in bulk region
- Using gradient-regulated asymptotic correction (GRAC) scheme to connect PBE0 and LB94 with the switching function $f[g(\boldsymbol{r})]$:

$$v_{xc}^{\text{GRAC}} = \{1 - f[g(\boldsymbol{r})]\}\, v_{xc}^{\text{PBE0}} + f[g(\boldsymbol{r})]v_{xc}^{\text{LB94}}$$

$$f[g(\boldsymbol{r})] = \left(1 + e^{-\alpha[g(\boldsymbol{r}) - \beta]}\right)^{-1}$$

$$g(\boldsymbol{r}) = \frac{|\nabla \rho(\boldsymbol{r})|}{\rho^{4/3}(\boldsymbol{r})}$$
GRAC & Long-Range Behavior

Figure: Radial densities $r^2\rho(r)$ of Ne atom (right) and errors compared to CCSD(T) density (left) for various xc potentials.[1]

Exchange-Dispersion Refitting

- ▶ Need to fit the uncoupled $E^{(2)}_{exch-disp,r}$ with non-LHF orbitals on the coupled LHF orbital values (implemented in Molpro)

- ▶ Assuming coupled LHF and non-LHF orbital $E^{(2)}_{exch-disp,r}$ from the behavior of $E^{(2)}_{disp,r}$

- ▶ Exchange-related components depend heavily on distance between monomers, sets like S22×5 and S66×8 would be preferred

- ▶ Determine the scaling factor with S22×5, validate with S66×8

S22×5 Fitting Results
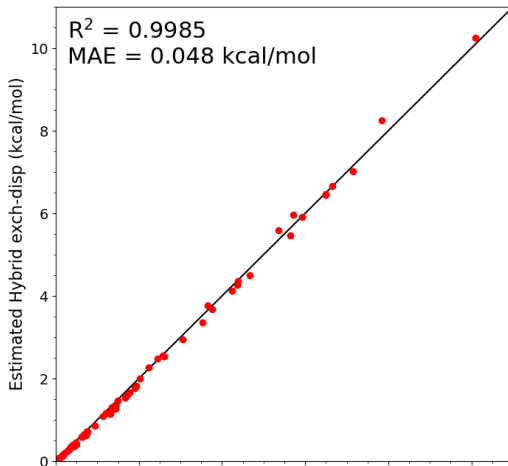

S66×8 Validating Results
Termwise results

▶ Compared the SAPT(DFT)/aug-cc-pVTZ results of our code to SAPT(CCSD)/aug-cc-pVTZ results from Korona S2[2], which consists of 14 small dimers

▶ Also comparing the results for S66. SAPT(CCSD) results are not available, used SAPT2+3(CCD)δMP2/aug-cc-pVTZ as reference. Also added SAPT0/aug-cc-pVDZ, SAPT2+/aug-cc-pVDZ and SAPT2+(3)δMP2/aug-cc-pVTZ into comparison as side-reference.

▶ Errors of each system with respect to reference shown as vertical lines

▶ Mean absolute error (MAE) and mean unsigned relative error (MURE) listed for S2

▶ Color scheme for S66 systems: Hydrogen-bonded (HB, red), mixed-influence (MX, green), dispersion-dominated (DD, blue)

Comparison with LHF Approach

TABLE IV. Wall times (in hours) for SAPT(DFT) computations of RDX dimer/aug-cc-pVTZ with hybrid and LHF algorithm.

Subroutine	Hybrid	LHF
Delta HF	0.96	N/A[a]
DFT	0.45	2.29
xc kernel	0.08	4.17
FDDS object[b]	2.35	N/A
Disp time integration	0.37	3.59
Exch-disp	0.41	1.99
Total	5.03	12.80

[a] The δHF correction, recommended for SAPT(DFT) computations of polar molecules, is performed by default in Psi4 but not in Molpro.

[b] Including integral transformation, form X/form Y (the $O(N^5)$ part) and QR factorization. In Molpro, the integral transformation is integrated with other terms, and the other steps are not relevant for LHF.
